

A new operation on finite partially ordered sets inherited from the random poset

Csaba Szabó
Eötvös Loránd University, Hungary

Joint with András Pongrácz

Recently, the structures first-order definable from the random partially ordered set were characterized. One of these structures was constructed via a new class of operations on partially ordered sets called rotations. These operations can be naturally restricted to finite posets. We investigate the basic combinatorial properties of rotation equivalence classes of finite posets.
