

# Why have we dented the circles

Gábor CZÉDLI

Szeged, October 27, 2016 (Kerékjártó Seminar, Department of  
Geometry)

For  $x \in L$ , the join of all covers of  $x$  is denoted by  $x^*$ . If, for all  $x, y, z \in L$ ,  $x \wedge y = x \wedge z$  implies  $x \wedge y = x \wedge (y \vee z)$ , then  $L$  is *meet-semidistributive*. If  $J_i L$  is the union of two chains, then  $L$  is *slim*. The next statement is known and gives a good understanding of join-distributive lattices within lattice theory. For further characterizations, see S. P. Avann [8], which is recalled in P. H. Edelman [16, Theorem 1.1], and see also M. Stern [22, Theorem 7.2.27].

## Proposition

*For a finite lattice  $L$ , the following properties are equivalent.*

- ▶  *$L$  is join-distributive, that is, semimodular and meet-semidistributive.*
- ▶  *$L$  has unique meet-irreducible decompositions.*
- ▶ *For each  $x \in L$ , the interval  $[x, x^*]$  is distributive.*
- ▶ *For each  $x \in L$ , the interval  $[x, x^*]$  is boolean.*
- ▶ *The length of each maximal chain of  $L$  equals  $|\text{Mi } L|$ .*
- ▶  *$L$  is semimodular and diamond-free.*
- ▶  *$L$  is semimodular and has no cover-preserving diamond sublattice.*
- ▶  *$L$  is a cover-preserving join-subsemilattice of a finite distributive lattice.*

The concept of antimatroids is due to R. E. Jamison-Waldner [18], who was the first to use the term “antimatroid”. At the same time, an equivalent complementary concept was introduced by P. H. Edelman [15] under the name “anti-exchange closures”. There are several ways to define antimatroids, see D. Armstrong [7, Lemma 2.1]; here we accept the following one. The set of all subsets of a set  $E$  is denoted by  $P(E)$ .

The concept of antimatroids is due to R. E. Jamison-Waldner [18], who was the first to use the term “antimatroid”. At the same time, an equivalent complementary concept was introduced by P. H. Edelman [15] under the name “anti-exchange closures”. There are several ways to define antimatroids, see D. Armstrong [7, Lemma 2.1]; here we accept the following one. The set of all subsets of a set  $E$  is denoted by  $P(E)$ .

### Definition

A pair  $\langle E, \mathfrak{F} \rangle$  is an *antimatroid* if it satisfies the following properties:

- ▶  $E$  is a finite set, and  $\emptyset \neq \mathfrak{F} \subseteq P(E)$ ;
- ▶  $\mathfrak{F}$  is a *feasible set*, that is, for each nonempty  $A \in \mathfrak{F}$ , there exists an  $x \in A$  such that  $A \setminus \{x\} \in \mathfrak{F}$ ;
- ▶  $\mathfrak{F}$  is closed under taking unions;
- ▶  $E = \bigcup \{A : A \in \mathfrak{F}\}$ .

Now, we define a concept closely related to antimatroids, see P.H. Edelman [15] and K. Adaricheva, V. A. Gorbunov, and V. I. Tumanov [?].

### Definition

A pair  $\langle E, \Phi \rangle$  is a *convex geometry*, also called *anti-exchange system*, if it satisfies the following properties:

- ▶  $E$  is a finite set, and  $\Phi: P(E) \rightarrow P(E)$  is a closure operator.
- ▶ If  $\Phi(A) = A \in P(E)$ ,  $x, y \in E$ ,  $x \notin A$ ,  $y \notin A$ ,  $x \neq y$ , and  $x \in \Phi(A \cup \{y\})$ , then  $y \notin \Phi(A \cup \{x\})$ . (This is the so-called *anti-exchange property*.) **Saying it more clearly:** If  $x, y \notin P(A) = A$  and  $\{x\} \cup A$  and  $\{y\} \cup A$  span the same, then  $x = y$ .
- ▶  $\Phi(\emptyset) = \emptyset$ .

For a closures system  $\mathcal{C}$  on  $E$  with corresponding closure operator  $\Phi$ ,  $\langle E, \mathcal{C} \rangle$  is a *convex geometry* if so is  $\langle E, \Phi \rangle$  in the above sense. In what follows, the notations  $\langle E, \Phi \rangle$  and  $\langle E, \mathcal{C} \rangle$  can be used interchangeably for the same mathematical object. The members of  $\mathcal{C}$  are called *closed sets*.

### Proposition

Let  $E$  be a finite set, and let  $\emptyset \neq \mathcal{F} \subseteq P(E)$ . Then  $\mathfrak{A} = \langle E, \mathcal{F} \rangle$  is an *antimatroid* iff  $\mathfrak{A}^\delta = \langle E, \{E \setminus X : X \in \mathcal{F}\} \rangle$  is a *convex geometry*.

## Proposition

*If  $L$  is a join-distributive lattice and  $\mathfrak{A} = \langle E, \mathfrak{F} \rangle$  is an antimatroid, then the following three statements hold.*

- ▶  $\langle \mathfrak{F}, \subseteq \rangle$  is a join-distributive lattice; it is denoted by  $\text{LJd}(\mathfrak{A})$ .
- ▶  $\langle \text{Mi } L, \{\text{Mi } L \setminus \uparrow x : x \in L\} \rangle$  is an antimatroid; it is denoted by  $\text{Amat}(L)$ ,
- ▶  $\text{LJd}(\text{Amat}(L)) \cong L$  and  $\text{Amat}(\text{LJd}(\mathfrak{A})) \cong \mathfrak{A}$ .

For a lattice  $L$  of finite length, the set  $\{[a, b] : a \prec b, a, b \in L\}$  of prime intervals of  $L$  will be denoted by  $\text{PrInt}(L)$ . For  $[a, b], [c, d] \in \text{PrInt}(L)$ , we say that  $[a, b]$  and  $[c, d]$  are *consecutive* if  $\{a, b, c, d\}$  is a covering square, that is, a 4-element cover-preserving boolean sublattice of  $L$ . The transitive reflexive closure of the consecutiveness relation on  $\text{PrInt}(L)$  is an equivalence, and the blocks of this equivalence relation are called the *trajectories* of  $L$ ; this concept was introduced for some particular semimodular lattices in G. Czédli and E. T. Schmidt [14]. For distinct  $[a, b], [c, d] \in \text{PrInt}(L)$ , these two prime intervals are *comparable* if either  $b \leq c$ , or  $d \leq a$ .

## Proposition (Czédli and Adaricheva)

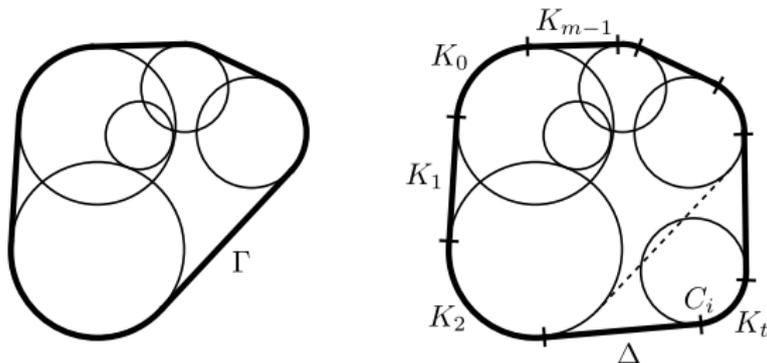

*For a semimodular lattice  $L$ , the following three conditions are equivalent.*

- ▶  *$L$  is join-distributive.*
- ▶  *$L$  is of finite length, and for every trajectory  $T$  of  $L$  and every maximal chain  $C$  of  $L$ ,  $|\text{PrInt}(C) \cap T| = 1$ .*
- ▶  *$L$  is of finite length, and no two distinct comparable prime intervals of  $L$  belong to the same trajectory.*

## Corollary

*Abstract convex geometries correspond to the DUAL of my favorite lattices.*

$\langle \mathbb{R}^n, \text{Conv}_{\mathbb{R}^n} \rangle$  is a convex geometry. Not every finite convex geometry can be embedded. Hence,

Circles (or disks) form a locally convex geometry (Czédli [11]); see the figure.  $\mathbb{R}^n$  also. Still not every finite convex geometry can be embedded (see later: Adaricheva and Bolat).

Richter and Rogers [21, Lemma 3]: polygons in  $\mathbb{R}^2$  do. Do they? Not satisfactorily ...

**Today's knowledge:** almost-circles give rise to representation (Czédli and Kincses), circles do not do that (Adaricheva and Bolat; shorter proof by Czédli),  $n$ -dimensional ellipsoids do (Kincses, few days ago).

Not known whether ellipses do (I am almost sure that they do not), or whether  $n$ -dimensional spheres do (I do not have a conjecture).

Czédli recently: the converse of Adaricheva and Bolat also holds (their property characterizes circles); in a sense, even a stronger result holds (congruence is sufficient, no similarity is needed).

## Theorem (Czédli and Kincses[13])

There exists a set  $T_{\text{new}}$  of some subsets of the plane, that is,  $T_{\text{new}} \subseteq \mathcal{P}(\mathbb{R}^2)$ , with the following properties.

- ▶ Every non-singleton member of  $T_{\text{new}}$  is a differentiable convex simple closed planar curve, and for all  $\vec{p} \in \mathbb{R}^2$ , the singleton  $\{\vec{p}\}$  belongs to  $T_{\text{new}}$ .
- ▶  $\langle T_{\text{new}}; \text{Conv}_{T_{\text{new}}} \rangle$  is a locally convex geometry.
- ▶  $T_{\text{new}}$  is closed with respect to non-degenerate affine transformations.
- ▶ For every finite convex geometry  $\langle E_0; \Phi_0 \rangle$  and for every (small) positive real number  $\varepsilon < 1$ , there exist continuum many pairwise affine-disjoint finite subsets  $E$  of  $T_{\text{new}}$  such that  $\langle E_0; \Phi_0 \rangle$  is isomorphic to the restriction  $\langle T_{\text{new}}; \text{Conv}_{T_{\text{new}}} \rangle|_E = \langle E; \text{Conv}_E \rangle$  and  $E$  consists of non-degenerate almost-circles of accuracy  $1 - \varepsilon$ .

Lemma ((†) and Theorems 5.1 and 5.2 in Edelman and Jamison [17])

(A) If  $\leq_1, \dots, \leq_t$  are linear orderings on a finite set  $E = \{1, 2, \dots, n\}$  and we define  $\mathfrak{G}$  as

$$\mathfrak{G} := \{\emptyset\} \cup \{X \in P(E) : (\forall y \in E \setminus X) (\exists i \in \{1, \dots, t\}) (X <_i y)\}, \quad (1)$$

then  $\langle E; \mathfrak{G} \rangle$  is a convex geometry.

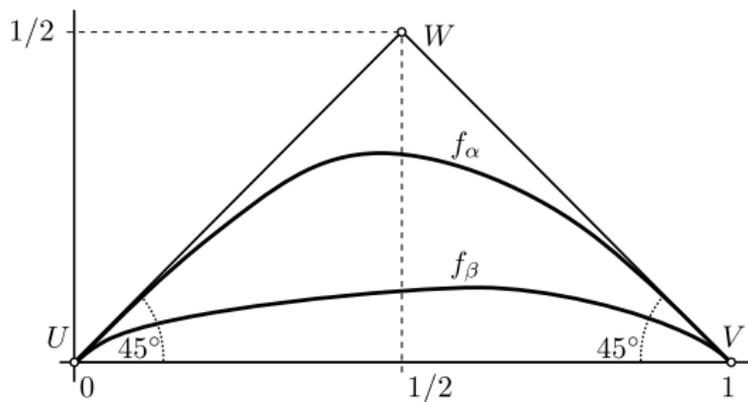

(B) Every finite convex geometry is isomorphic to some  $\langle E; \mathfrak{G} \rangle$  such that  $\mathfrak{G}$  is determined by finitely many linear orderings as in (1).

Next, we define the following polynomials and consider them functions  $[0, 1] \rightarrow \mathbb{R}$ :

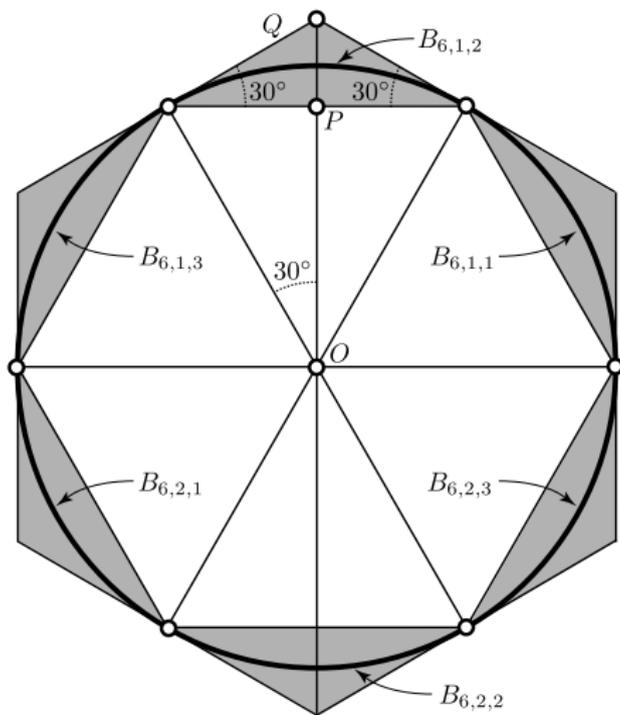

$$p(x) = x(1-x)(x^5 - x^4 + 1) = -x^7 + 2x^6 - x^5 - x^2 + x,$$

$$q(x) = x(1-x) = -x^2 + x, \text{ and, for } \alpha \in (0, 1),$$

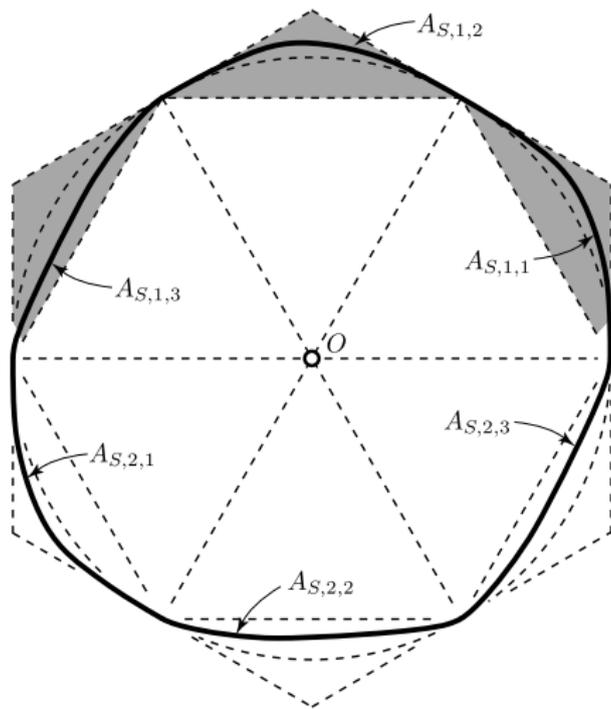

$$f_\alpha(x) = \alpha p(x) + (1-\alpha)q(x) = -\alpha x^7 + 2\alpha x^6 - \alpha x^5 - x^2 + x.$$

A affine-rigid family of functions

The unit circle with inscribed and circumscribed regular  $t$ -gons and  $mt = 6$  circular arcs.

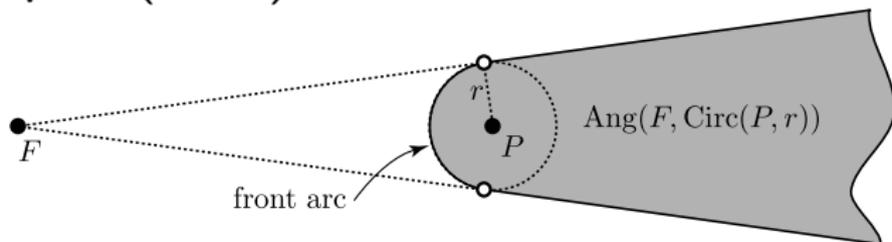

$C(\text{gf}F, S)$ , an almost-circle of accuracy  $1 - (\pi/6)^2 \approx 0.7258$

## Theorem (Adaricheva and Bolat [3])

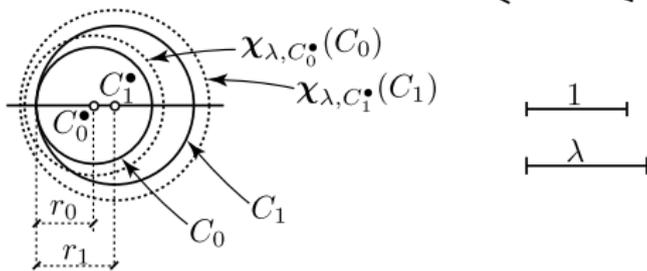

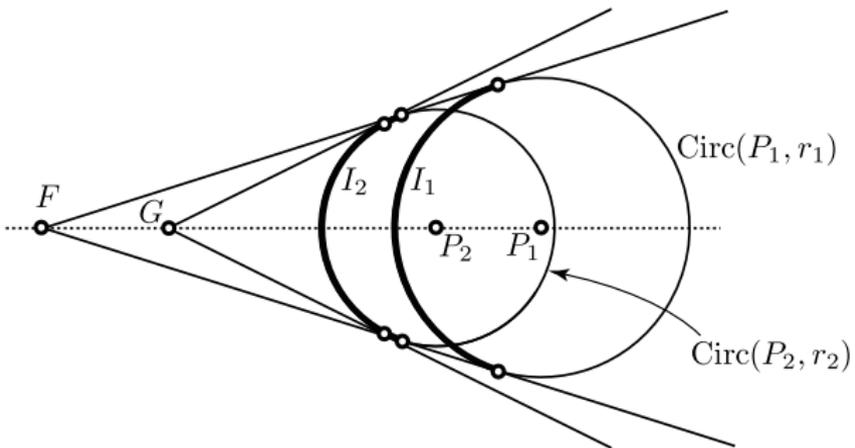

Let  $A_0, A_1, A_2$  be points in the plane. If  $U_0$  and  $U_1$  are circles such that  $U_i \subseteq \text{Conv}_{\mathbb{R}^2}(\{A_0, A_1, A_2\})$  for  $i \in \{0, 1\}$ , then there exist subscripts  $j \in \{0, 1, 2\}$  and  $k \in \{0, 1\}$  such that

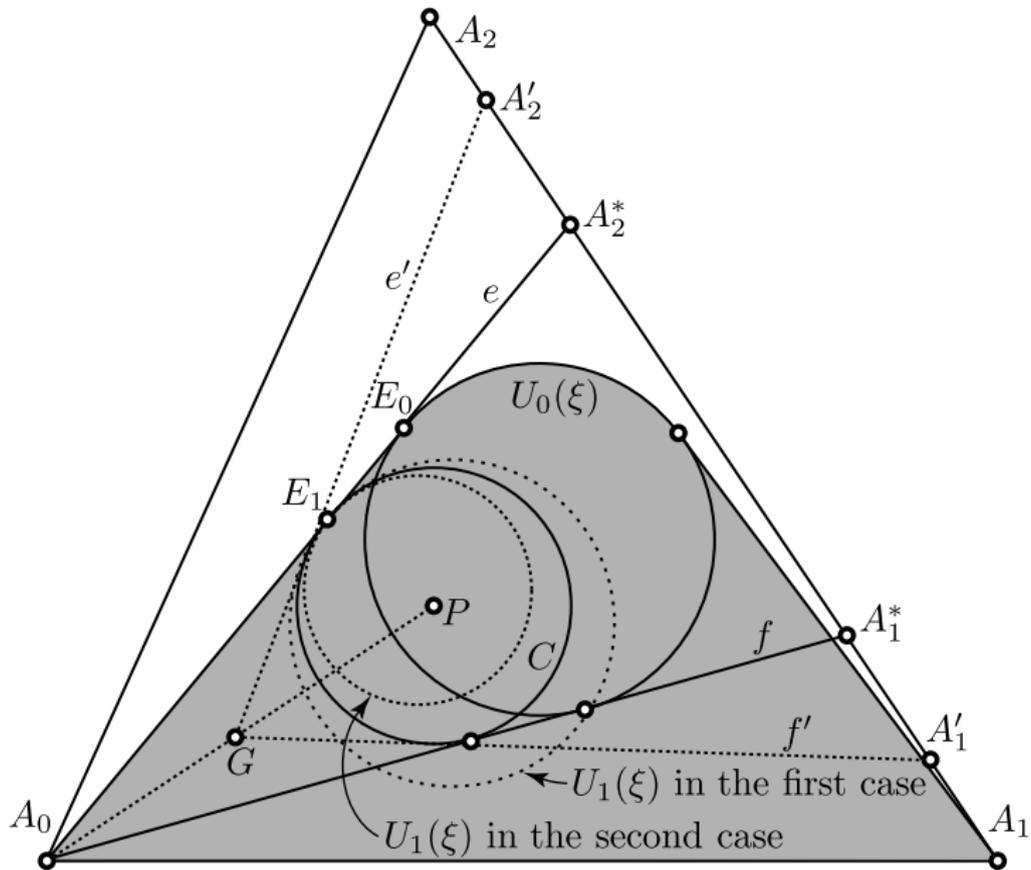

$$U_{1-k} \subseteq \text{Conv}_{\mathbb{R}^2}(U_k \cup (\{A_0, A_1, A_2\} \setminus \{A_j\})). \quad (2)$$

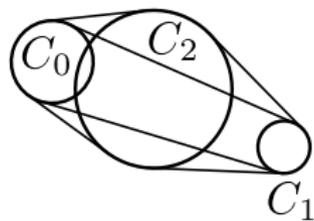

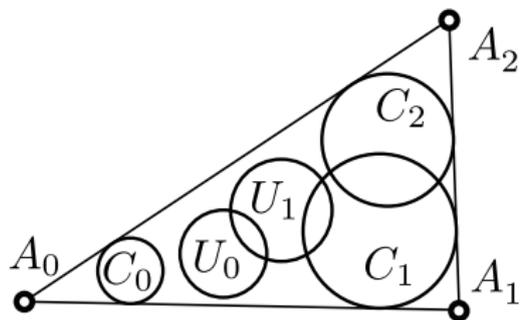

## Second proof (Czédli)

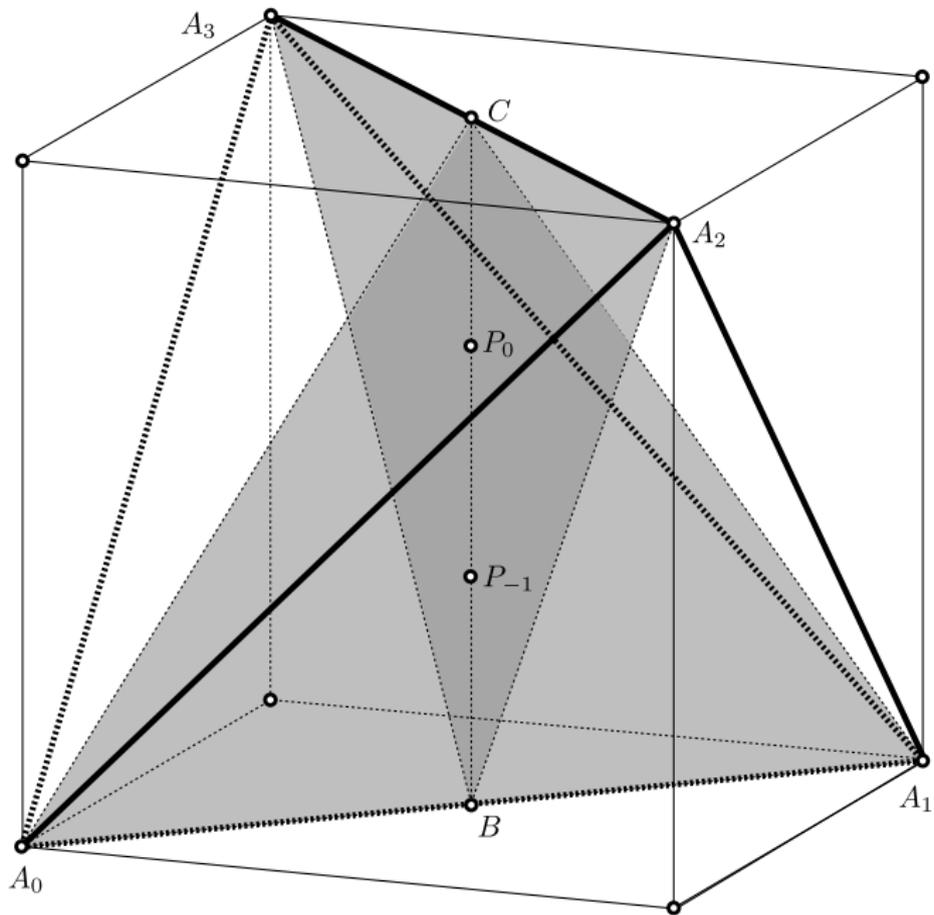

Round-edged angle

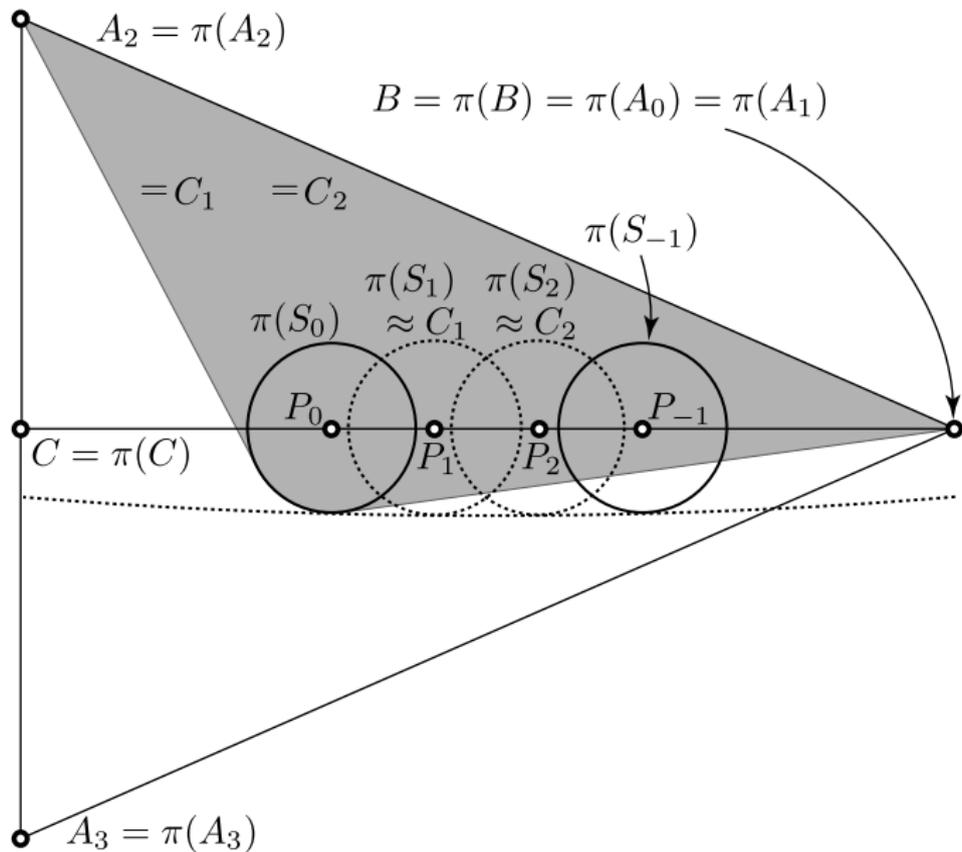

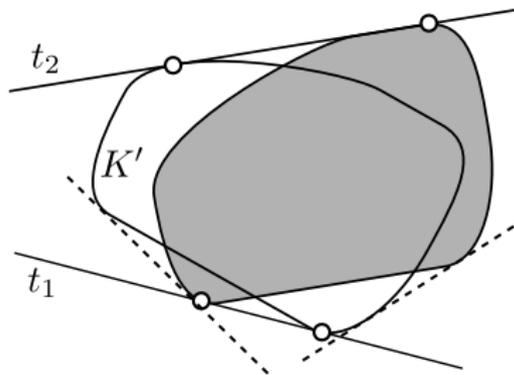

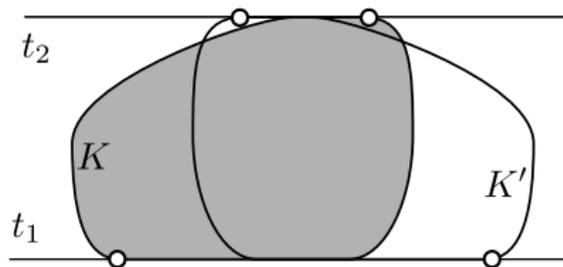

Circles instead the corners of the triangle

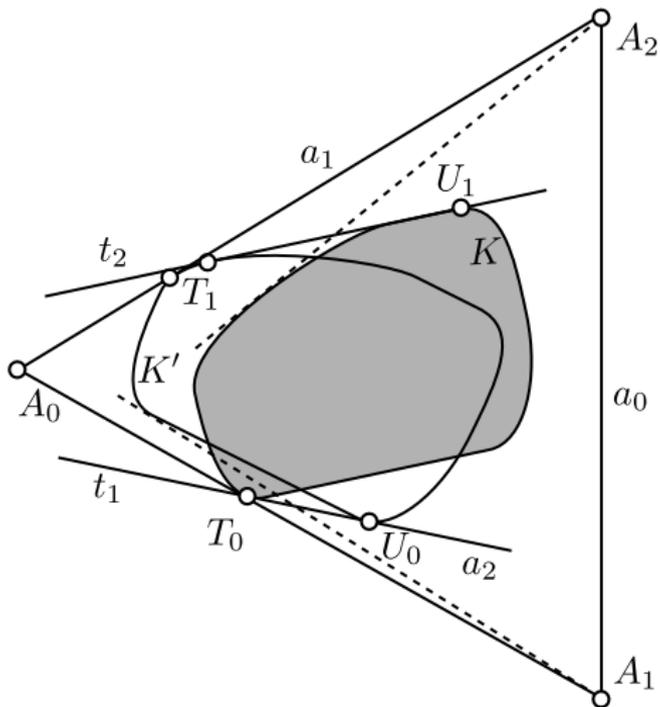

Spheres for which the property fails, because

it fails for their projected planar images

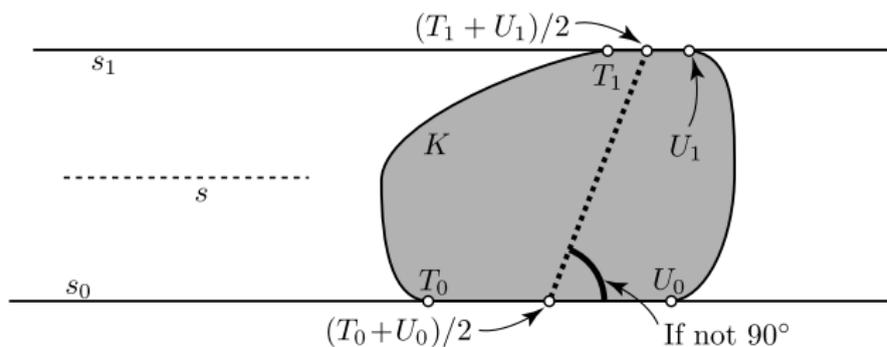

**Cross Lemma:** if the tangents are parallel, both directions are fine.

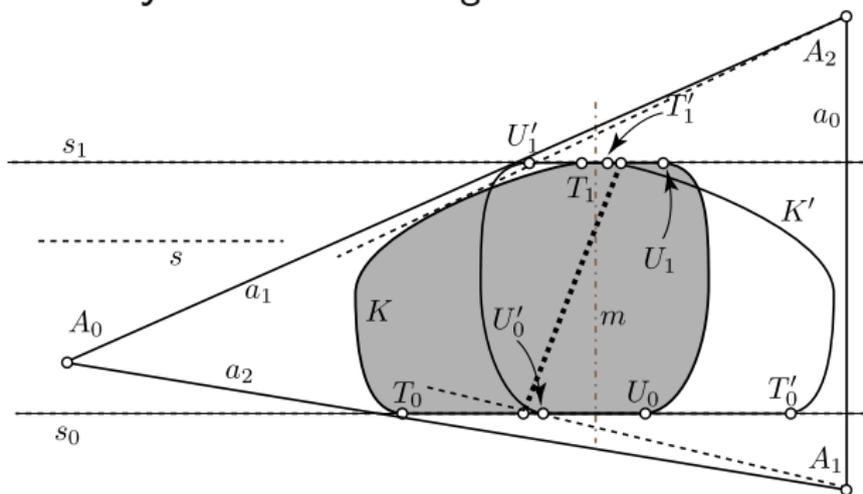

**Cross Lemma Proof:** tangently to  $K$  or  $K'$ , rotate the tangent lines slightly; clock-wise the lower one and anti-clockwise the upper one.

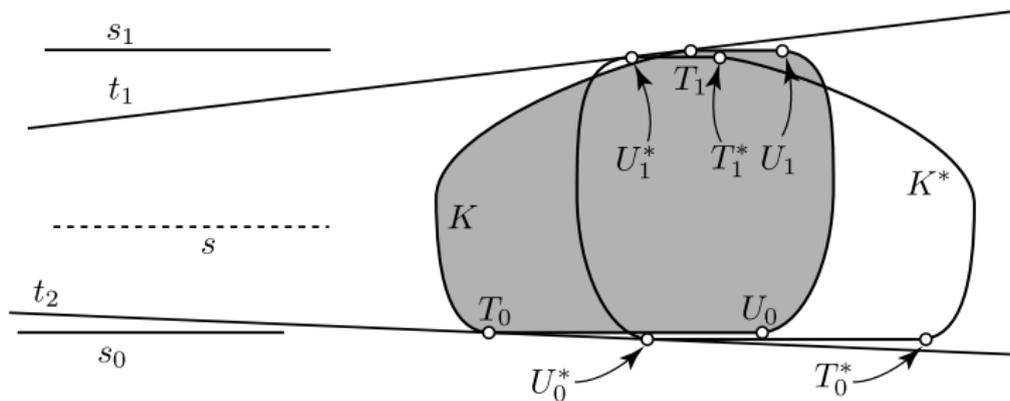

$T_1 \in K' \not\subseteq \text{Conv}(K \cup \{A_0, A_1\})$ ,  $U_0 \in K' \not\subseteq \text{Conv}(K \cup \{A_0, A_2\})$ ,  
 $T_1 \in K' \not\subseteq \text{Conv}(K \cup \{A_1, A_2\})$ , symmetric roles. Done.

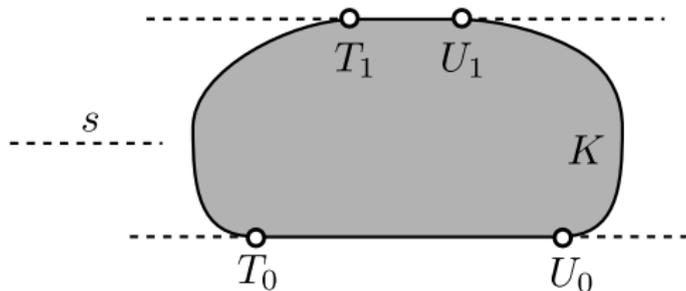

**Perpendicularity Lemma:** this angle must be  $90^\circ$ .

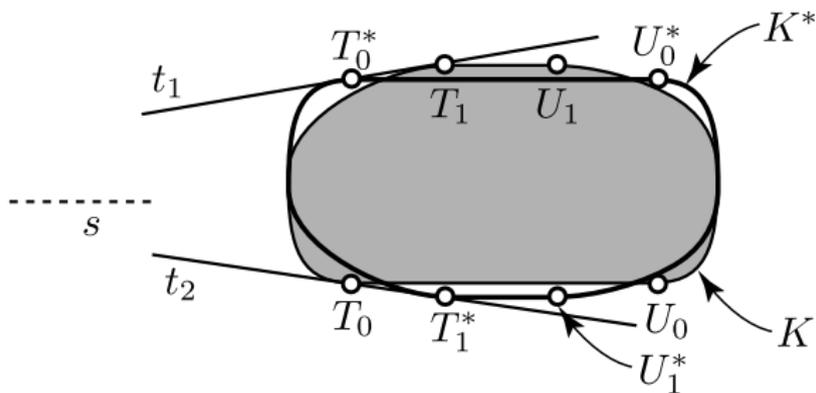

**Perpendicularity Lemma Proof:** reflect and Cross Lemma.

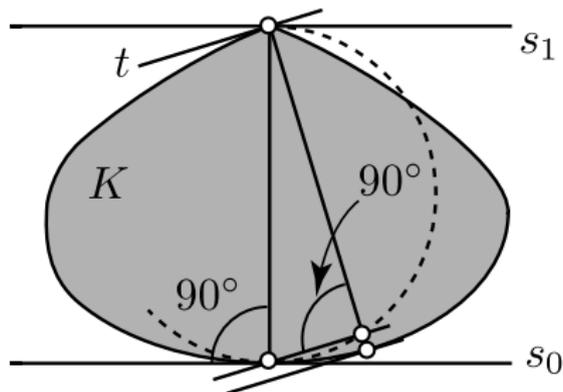

**Perpendicularity Lemma 2nd Proof** (also, exemplifies the "parallel" case of the Cross Lemma): see the figure above.

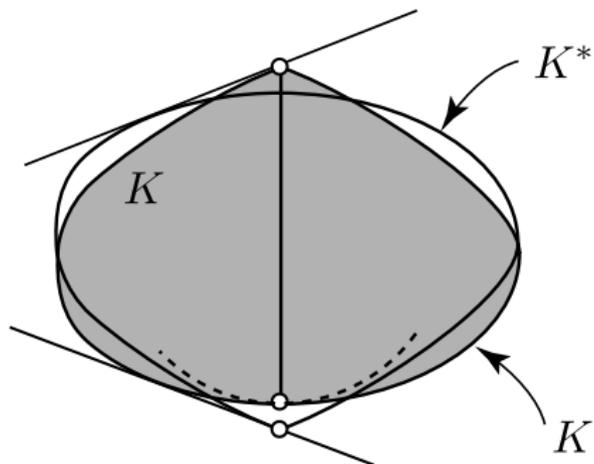

**Same Opposite Sides Lemma:**  $\text{dist}(T_0, U_0) = \text{dist}(T_1, U_1)$ .

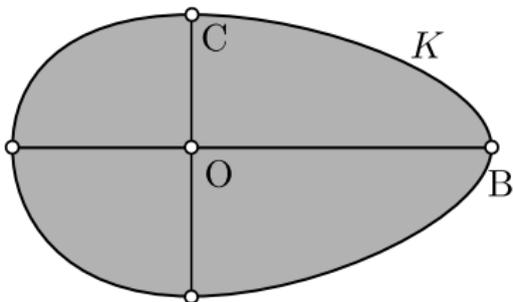

**Same Opposite Sides Lemma Proof:** reflect, shift slightly down, and Cross Lemma.

**No Corner Lemma Proof:** by the Perpendicular Lemma, the opposite of a corner cannot be inside a circular arc.

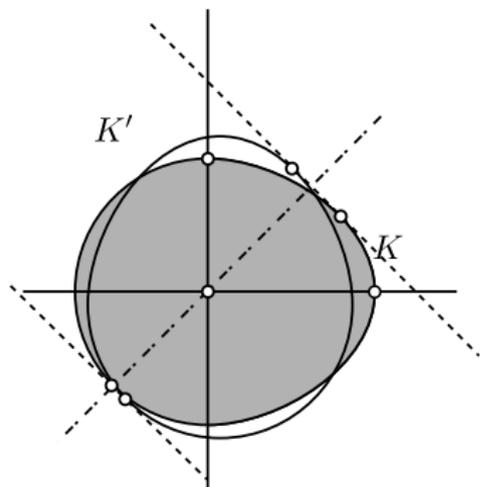

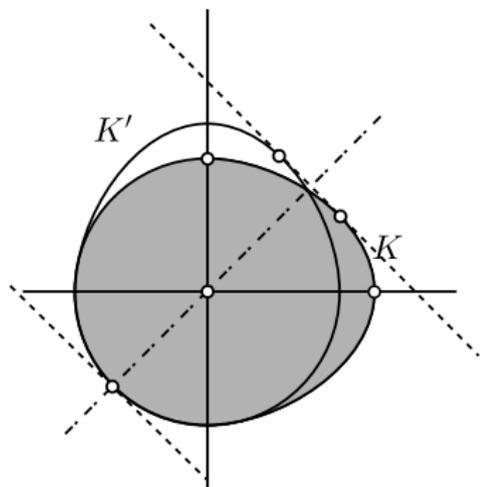

**No Corner Lemma Proof cont'd:** reflect across a horizontal axis, shift down a little, and apply the Cross Lemma. Q.e.d  
Diagonal (def): line segment between two opposite tangent points.

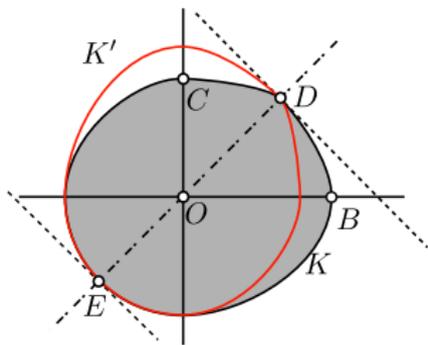

**Two Diagonals Lemma:** If  $O$  is the intersection of two diagonals, then  $\text{dist}(O, B) = \text{dist}(O, C)$ .

**Two Diagonals Lemma Proof/2:** A less easy case: excluded by the Perpendicularity Lemma.

**Two Diagonals Lemma Proof/3:** A difficult case: no similar shift can help: Then the tangents at  $D$  and  $E$  are kept fixed by the reflection,  $DE$  is also a diagonal. If  $\text{dist}(O, E) \neq \text{dist}(O, B)$ , then repeat the procedure with the diagonals through  $OE$  and  $OB$ , and also the diagonals through  $OE$  and  $OC$ . And so on, keep halving the angles. Either we get a good (or easy) case and the indirect proof becomes complete, or we got a dense set of diagonals through  $O$ . Since  $K$  is perpendicular to it, we have a slope field (direction field). The circle is a solution of the corresponding ODE, and by a classical uniqueness theorem, there is no other solution.
